Host: *Cafeteria roenbergensis*

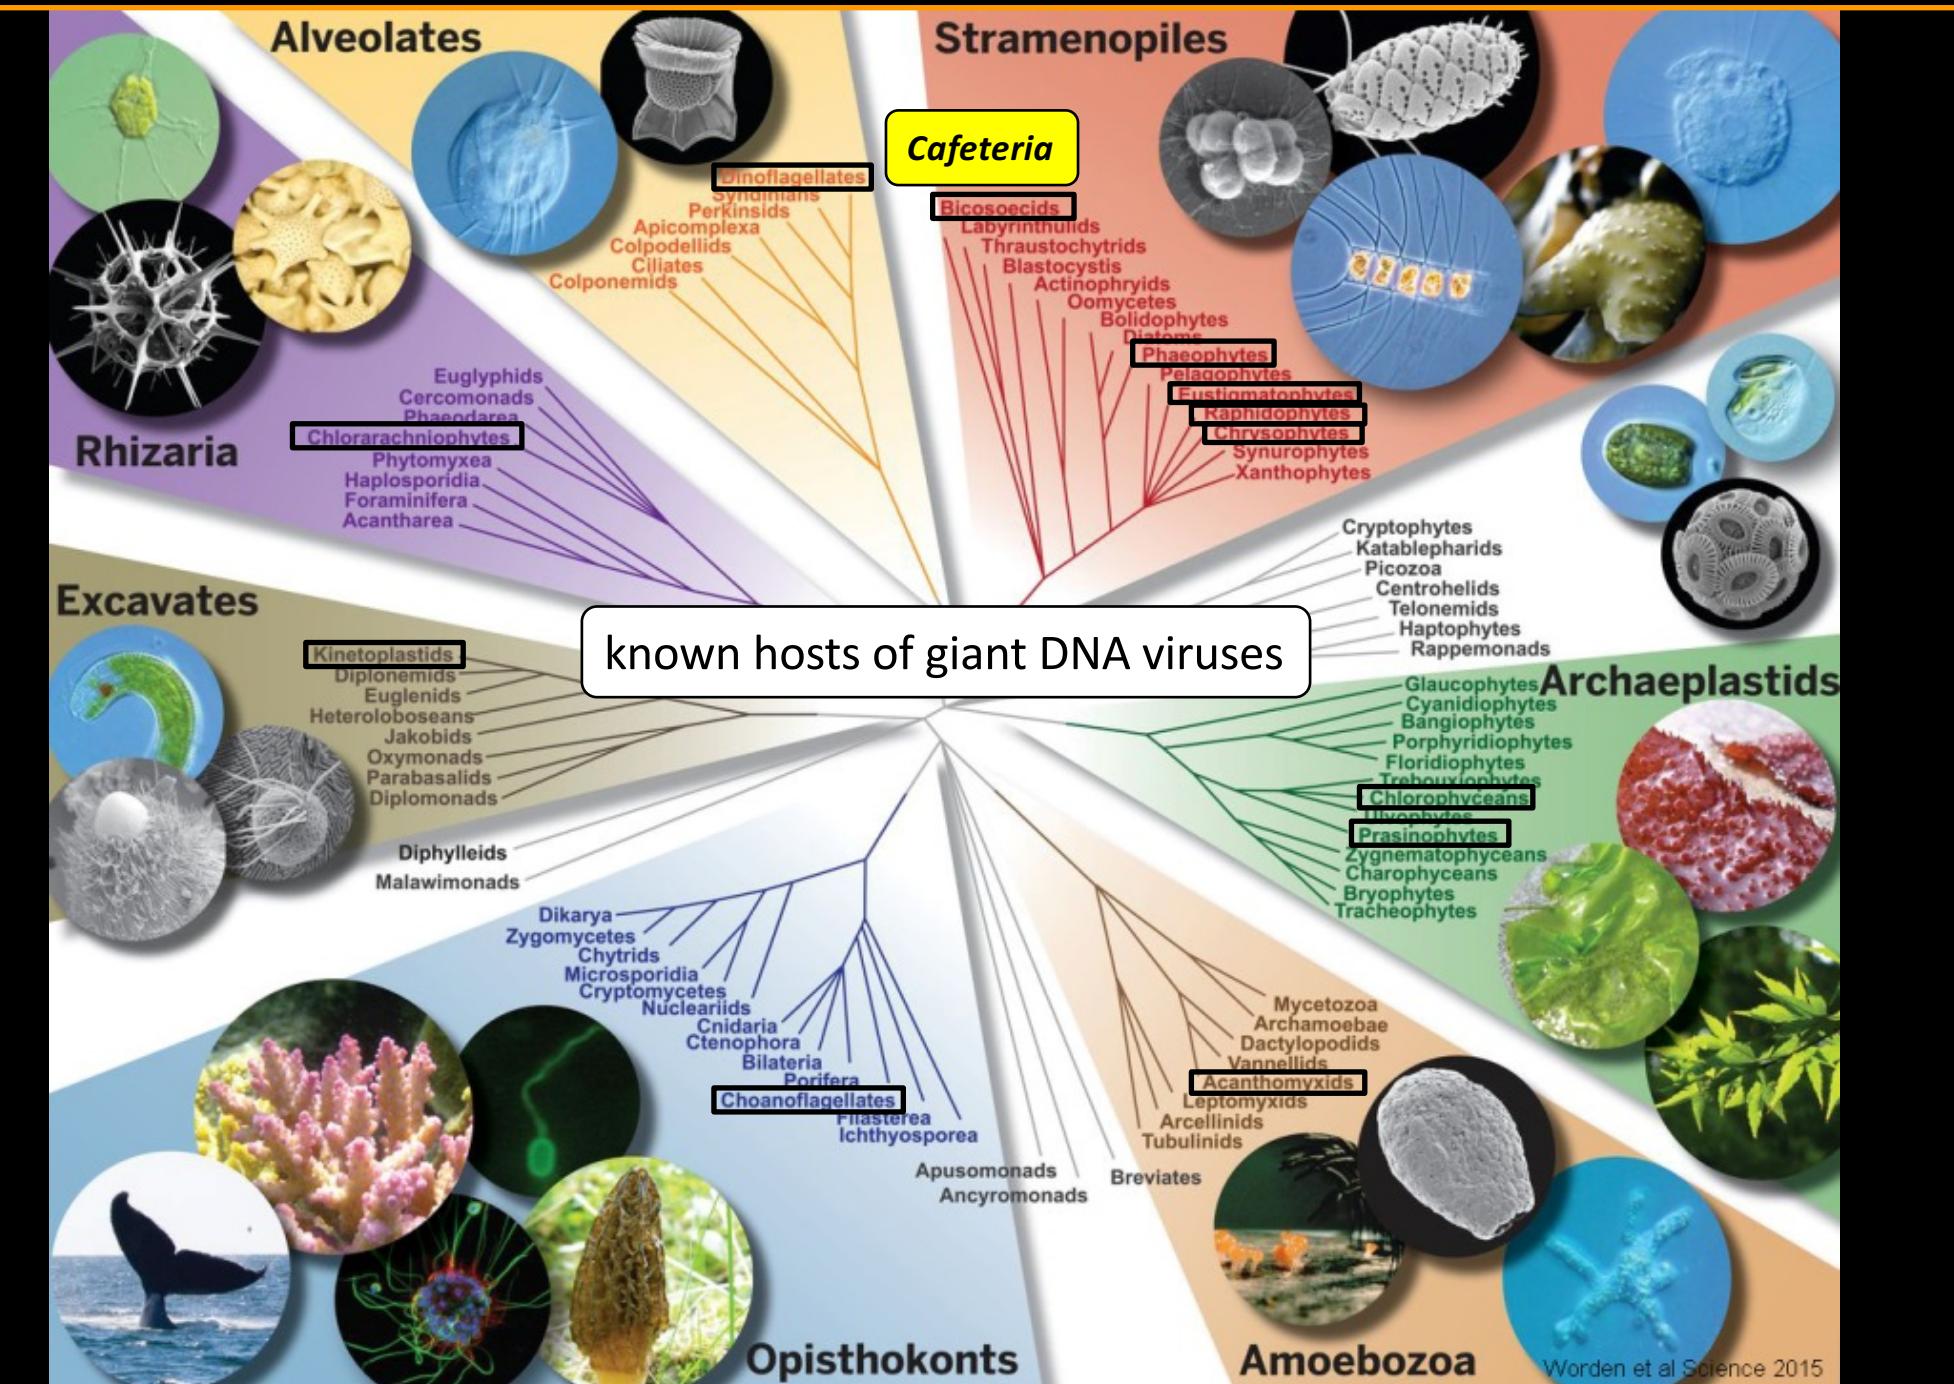

www.eol.org

- marine heterotrophic nanoflagellate
- ecologically important bacterivore
- Ø 5-10 µm
- 30 Mpb diploid genome, asexual (?)

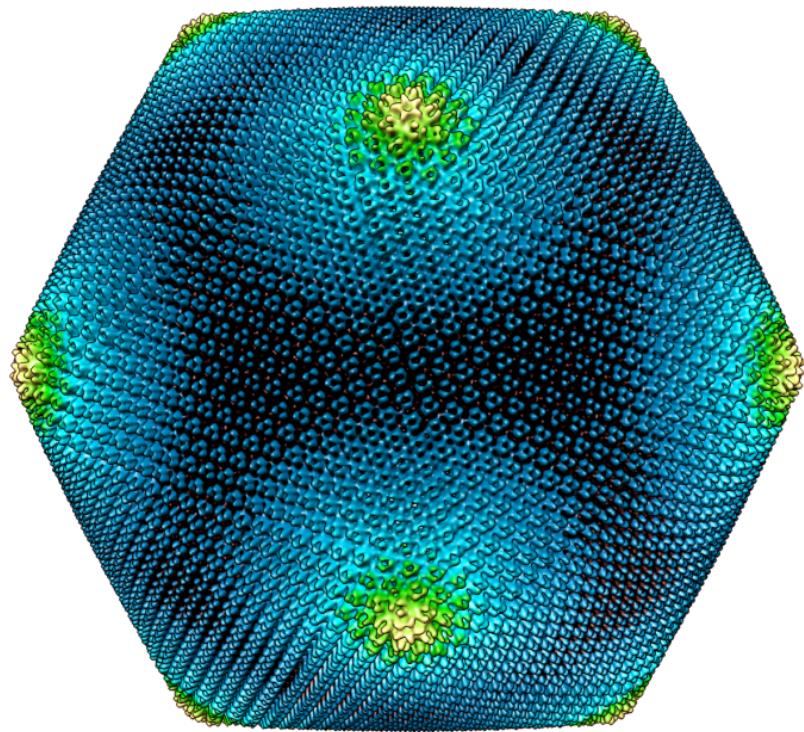

Cafeteria is a deep-branching stramenopile

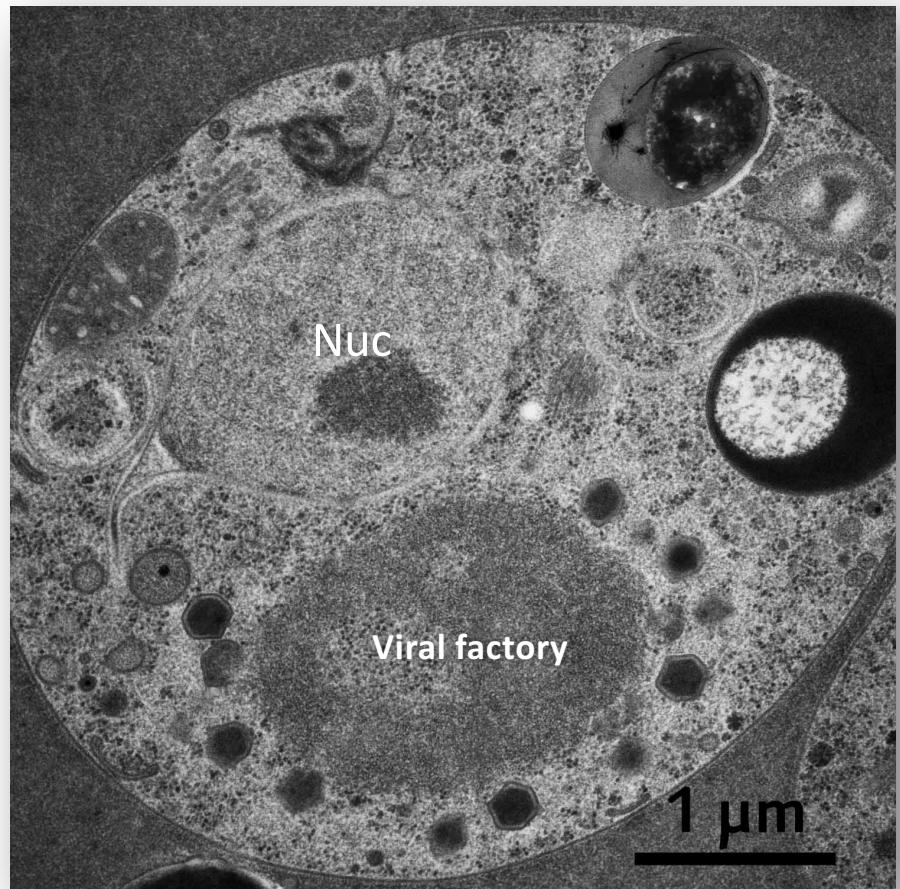

Parasite: Cafeteria roenbergensis virus (CroV)

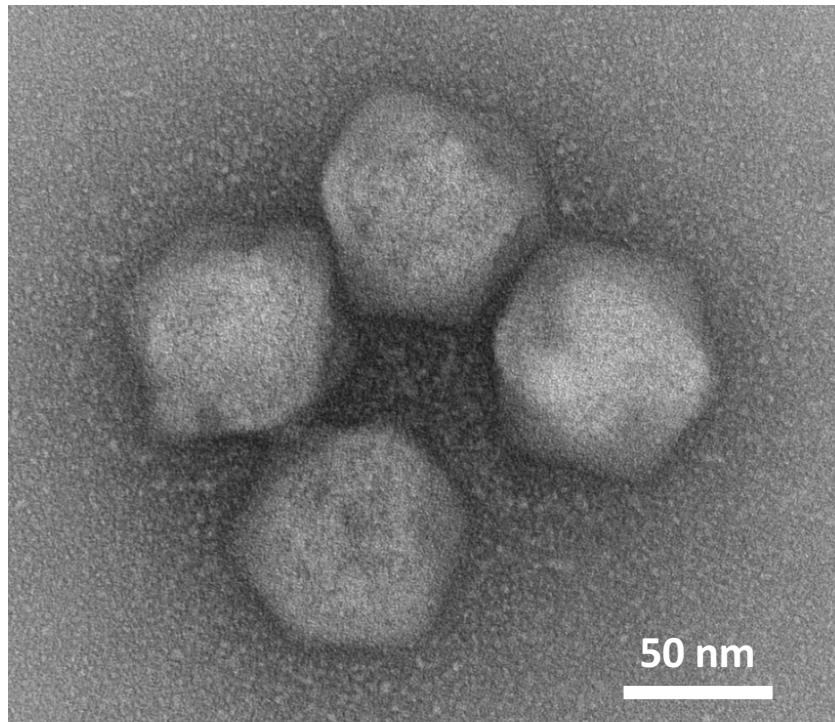

- capsid $\emptyset = 300$ nm
- T number = 499
- 691,790 bp dsDNA
- > 600 proteins
- 57 tRNA genes
- member of *Mimiviridae*

Electron microscopy by Ulli Mersdorf, MPImF

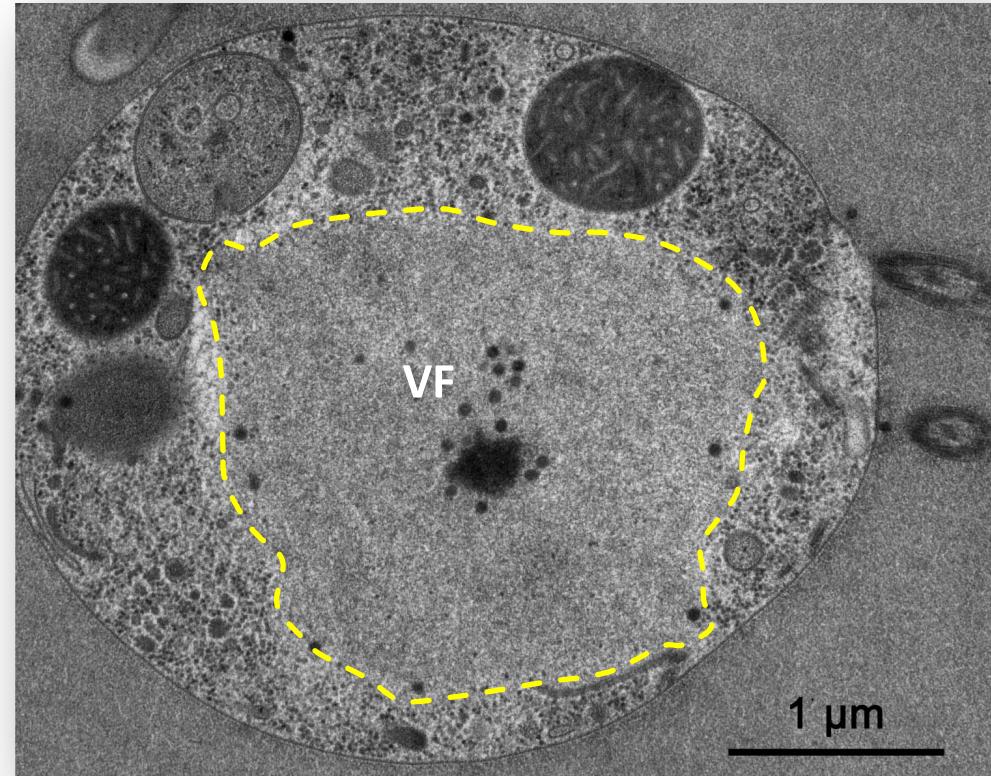

Hyperparasite: the virophage mavirus

capsid $\varnothing = 75 \text{ nm}$

19 kb dsDNA

20 ORFs

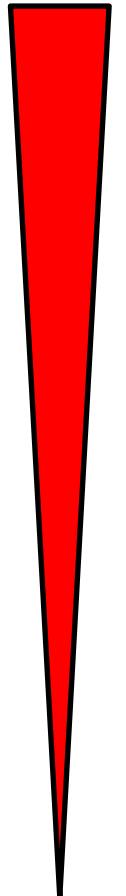

→ Mavirus is highly virulent for CroV

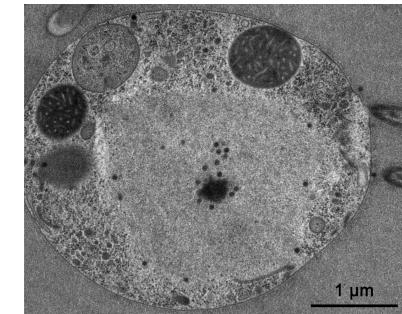

Virulence towards giant viruses varies among virophages

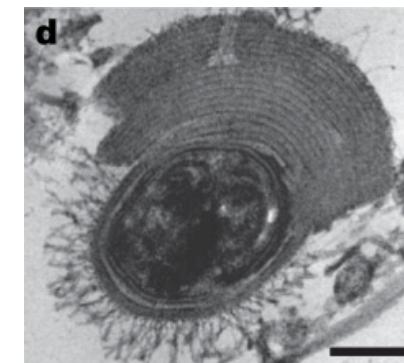

strong inhibition

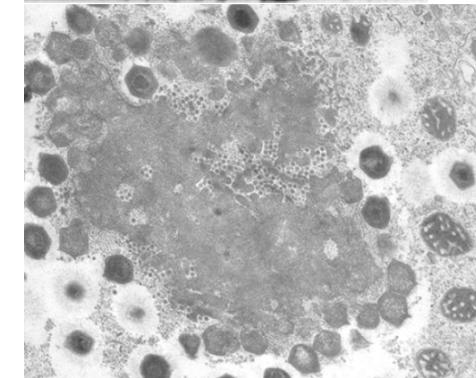

Mavirus — CroV

Sputnik — Mimivirus

Zamilon — Mimivirus

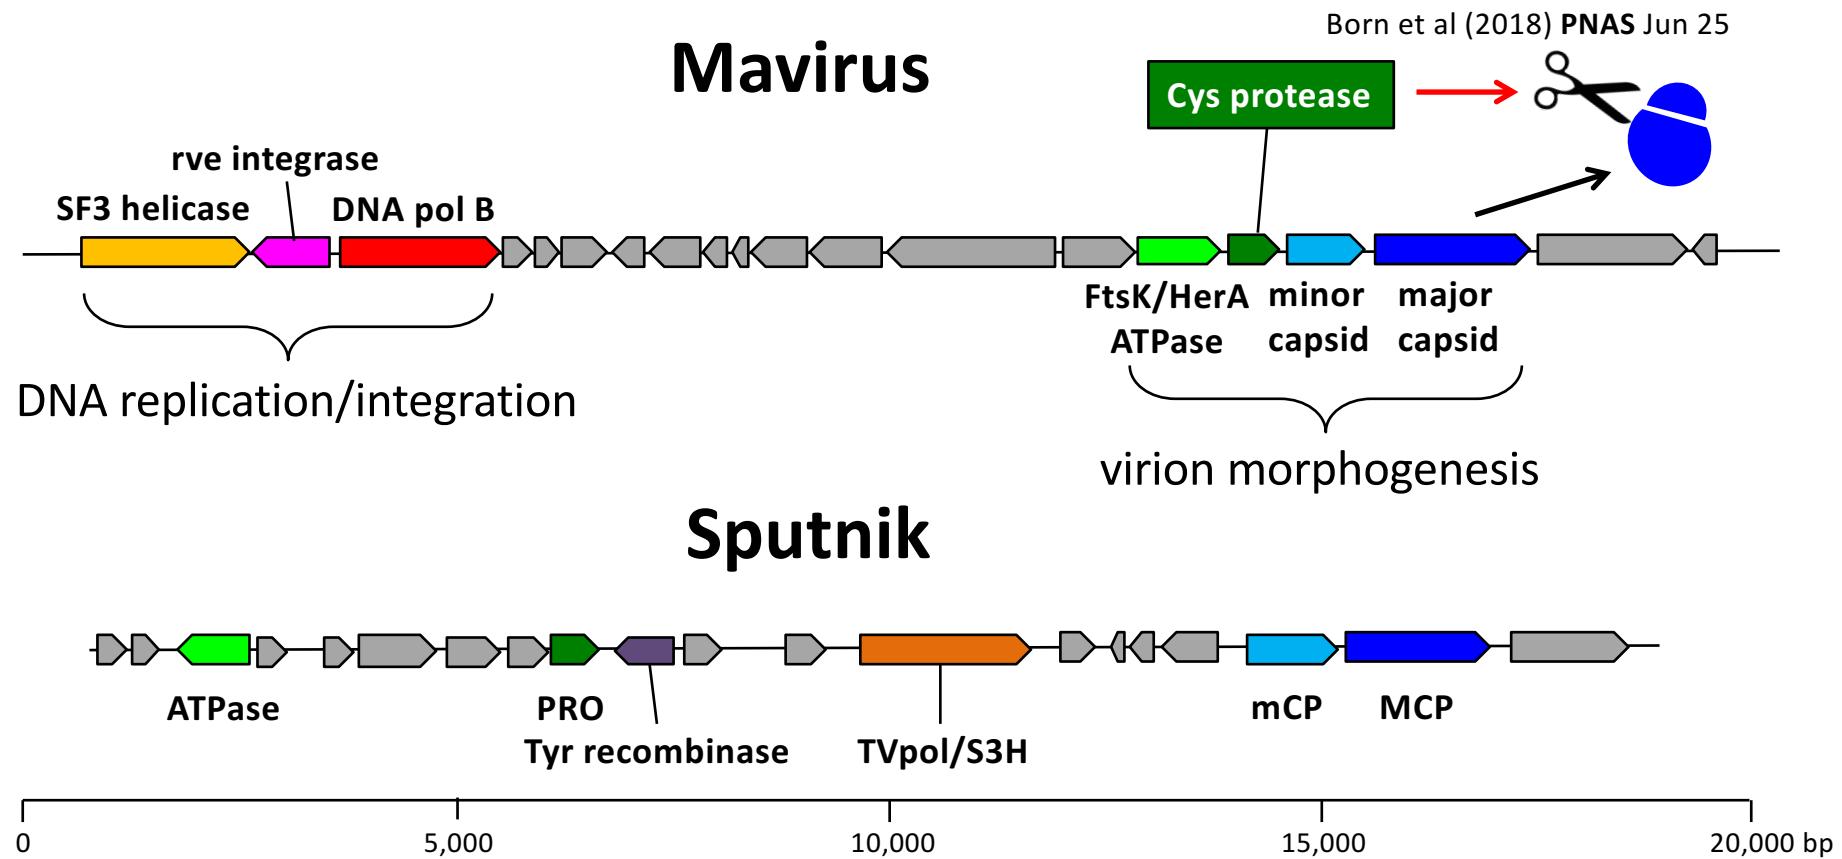

no inhibition

Fischer & Suttle (2011) **Science** 332:231
La Scola, Desnues et al (2008) **Nature** 455:100
Gaia et al (2014) **PLoS One** 9:e94923

Virophages genomes are modular

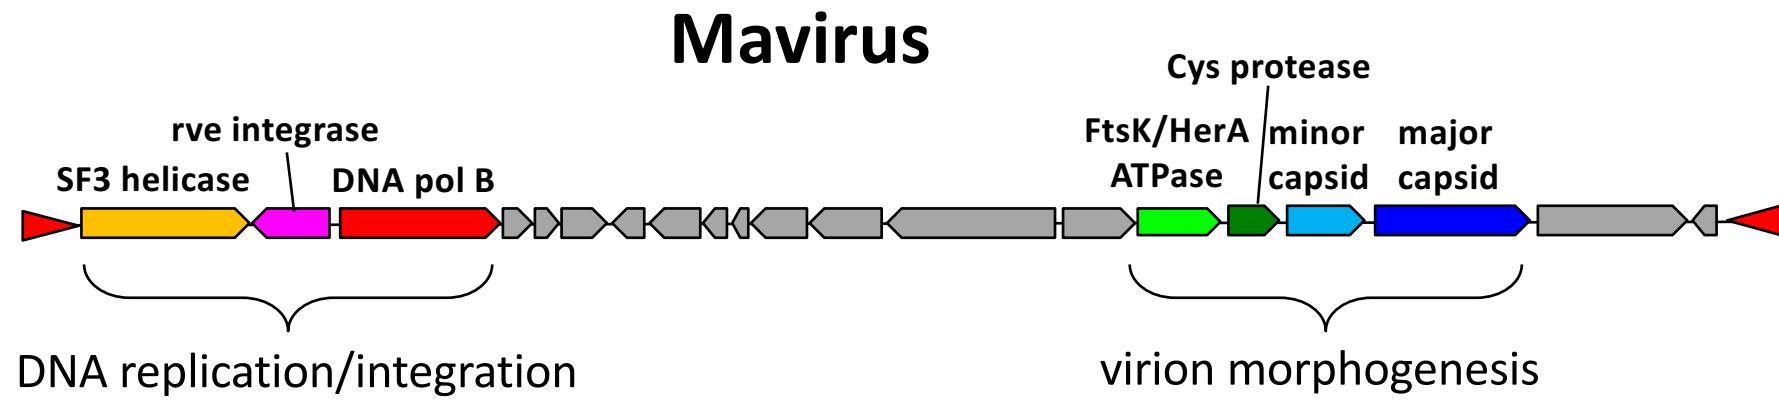

Conserved morphogenesis genes:

Mavirus is related to endogenous eukaryotic elements

Maverick/Polinton DNA transposons

- 15-20 kb long
- flanked by inverted repeats
- found in protists, nematodes, insects, vertebrates, fungi

Trichomonas vaginalis:
30% of genome are polintons

Feschotte & Pritham (2005) **Trends Genet** 21
Kapitonov & Jurka (2006) **PNAS** 103

Virophage genome integration

Sputnik integrated in mimivirus:

Provirophages and transpovirons as the diverse mobilome of giant viruses (2012) PNAS 109

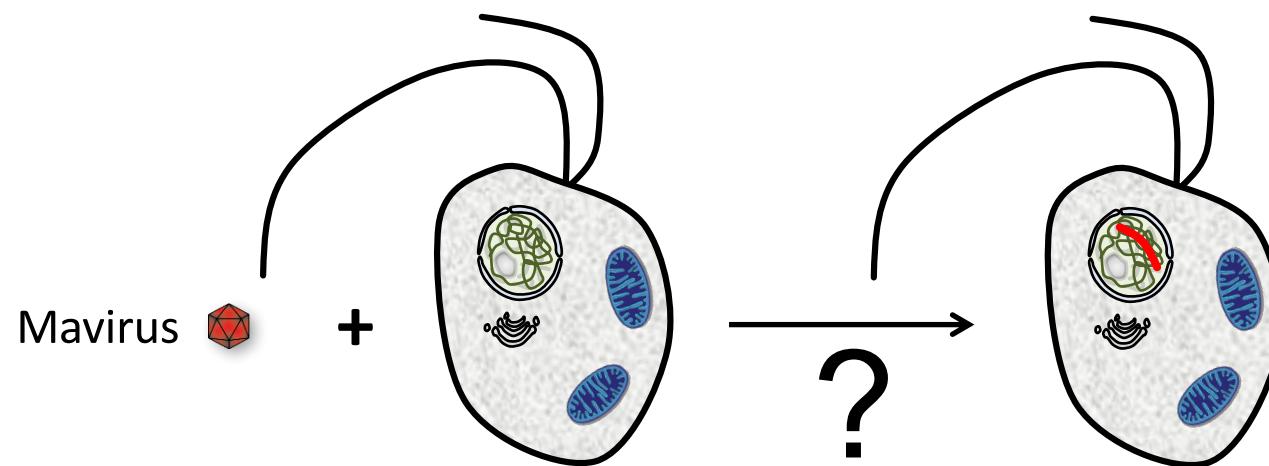

Christelle Desnues^{a,1}, Bernard La Scola^{a,1}, Natalya Yutin^b, Ghislain Fournous^a, Catherine Robert^a, Saïd Azza^a, Priscilla Jardot^a, Sonia Monteil^a, Angélique Campocasso^a, Eugene V. Koonin^b, and Didier Raoult^{a,2}

Endogenous virophages in an algal genome:

Provirophages in the Bigelowia genome bear testimony to past encounters with giant viruses

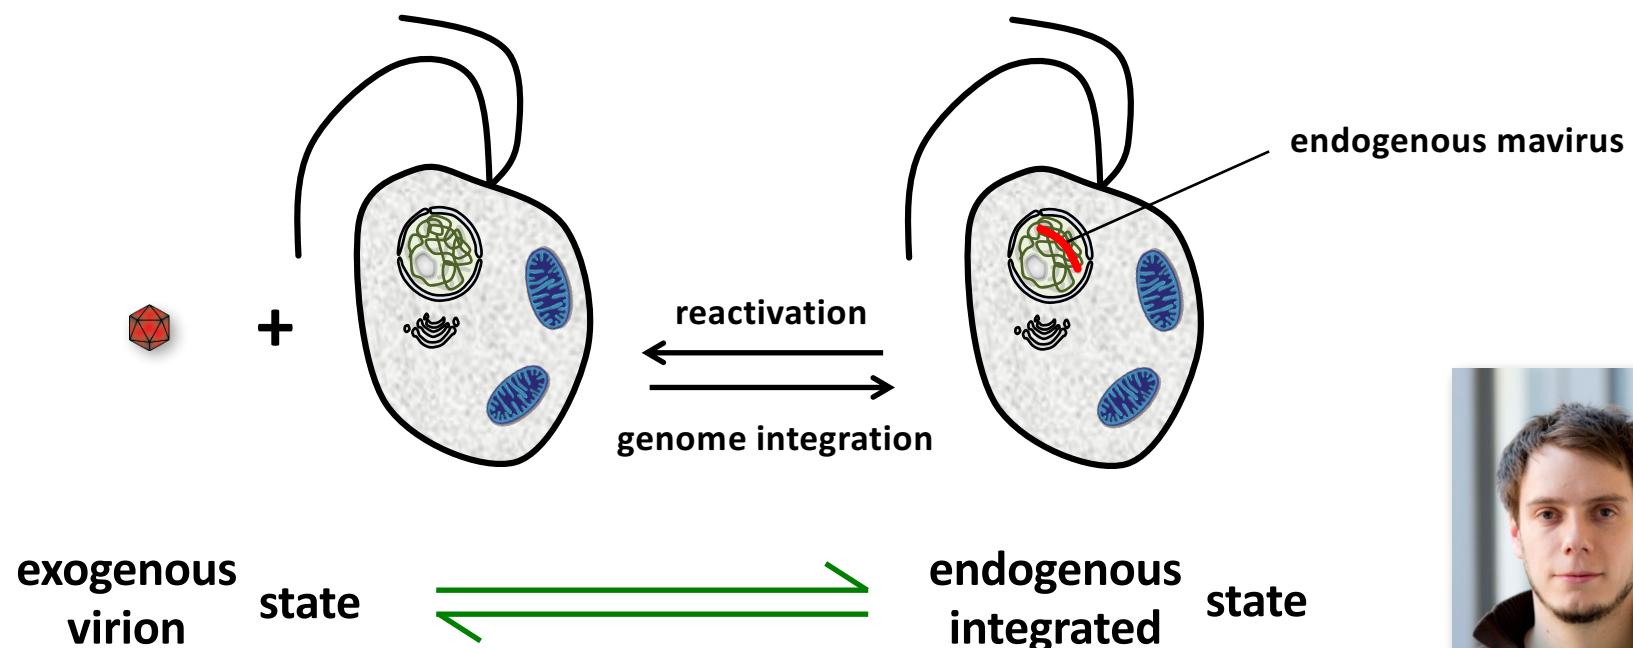

Guillaume Blanc^{a,1,2}, Lucie Gallot-Lavallée^a, and Florian Maumus^{b,1,2} (2015) PNAS 112

Endogenous mavirus in *Cafeteria* genome?

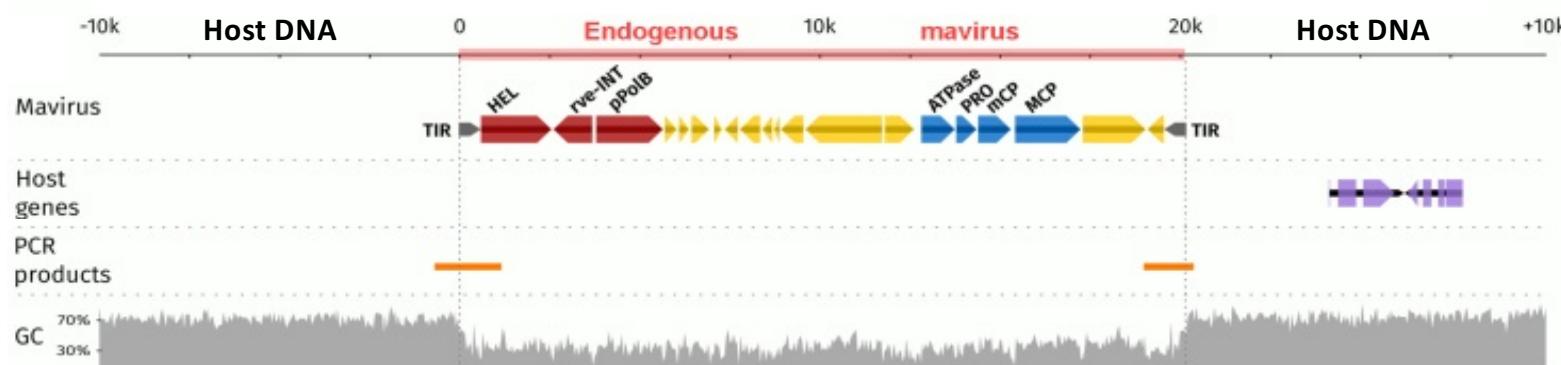

Mavirus integrates into the host genome

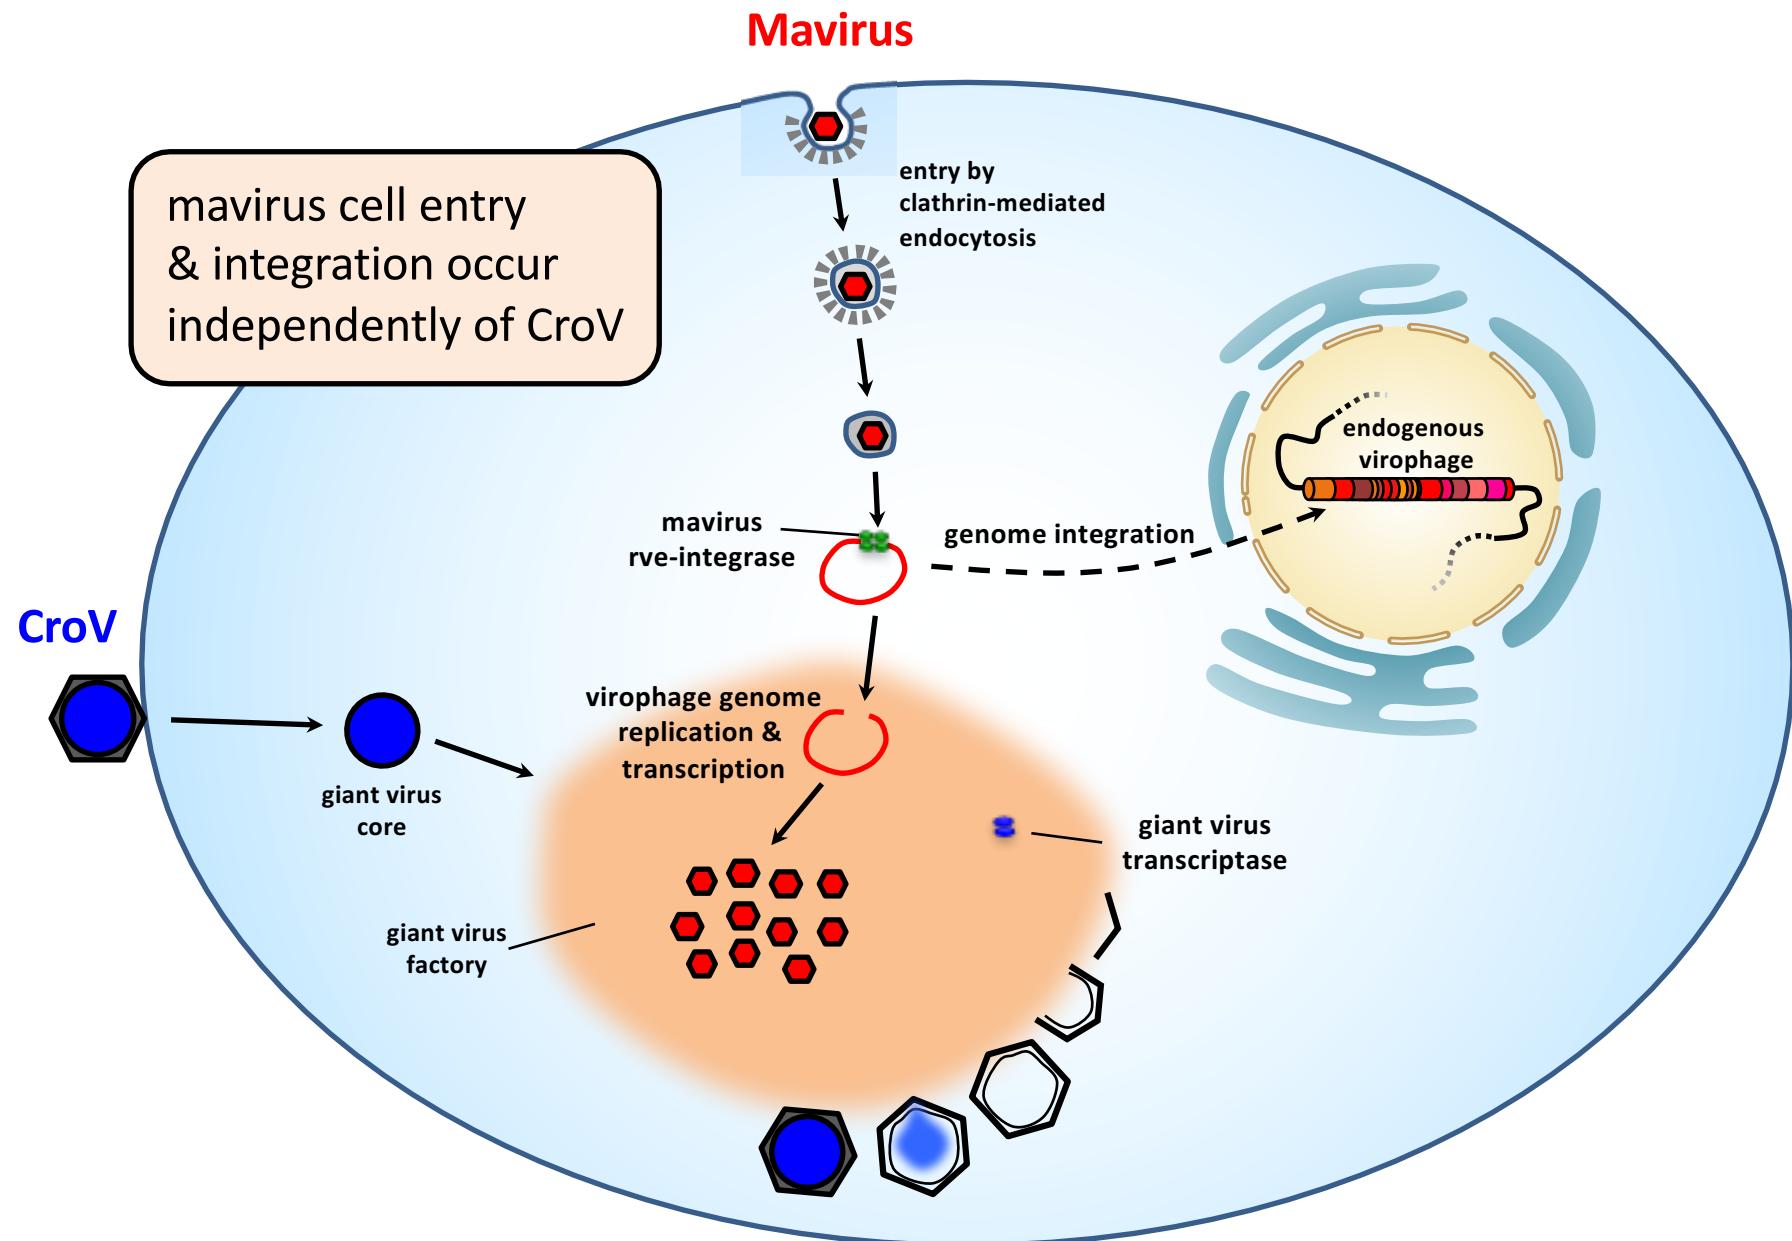

Thomas Hackl

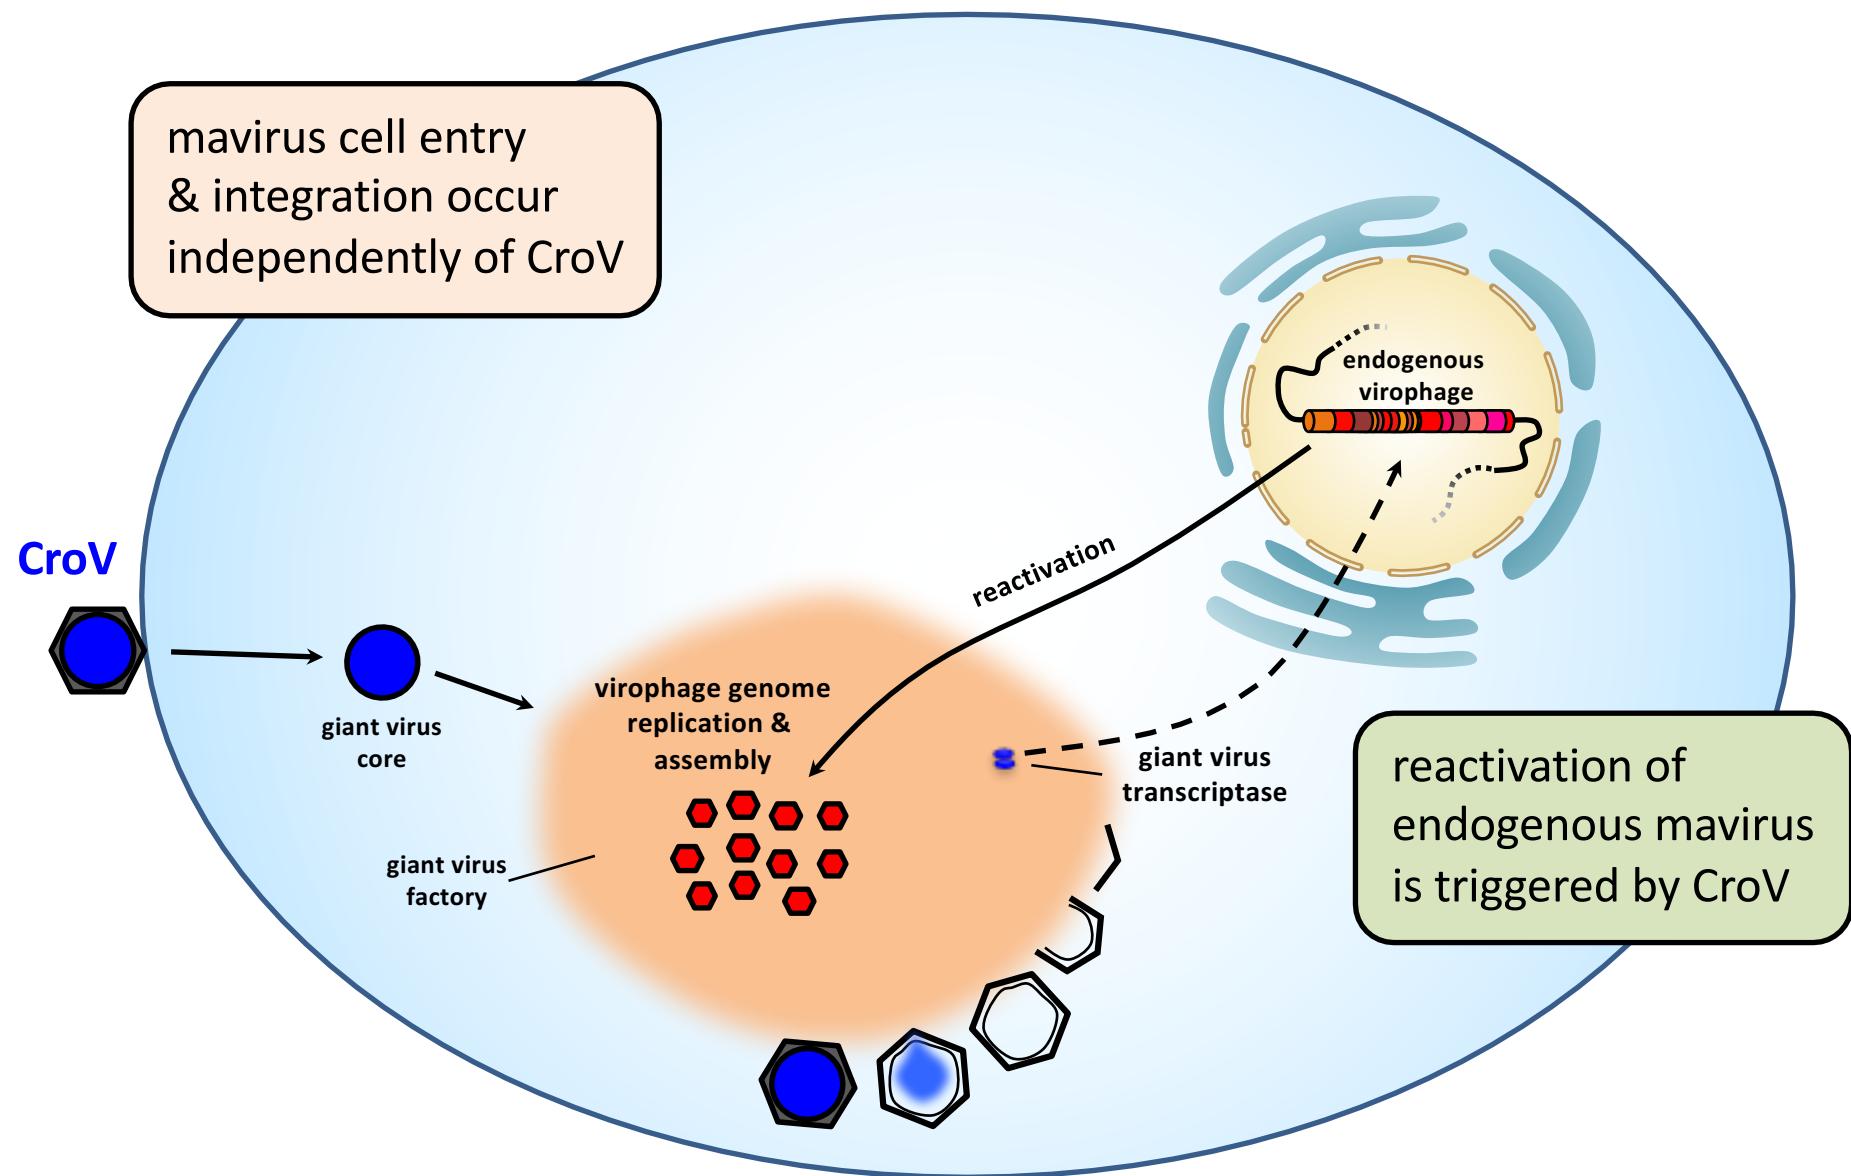

The mavirus infection cycle

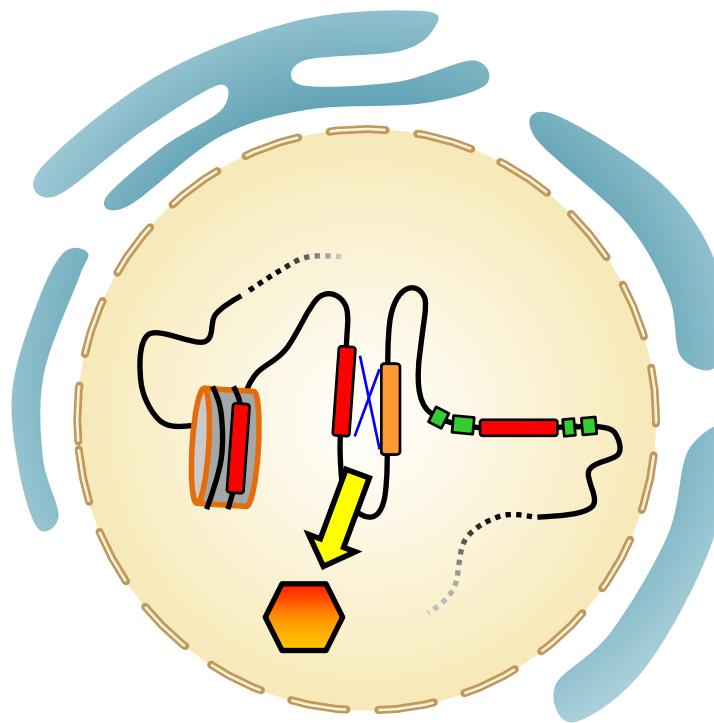

The mavirus infection cycle

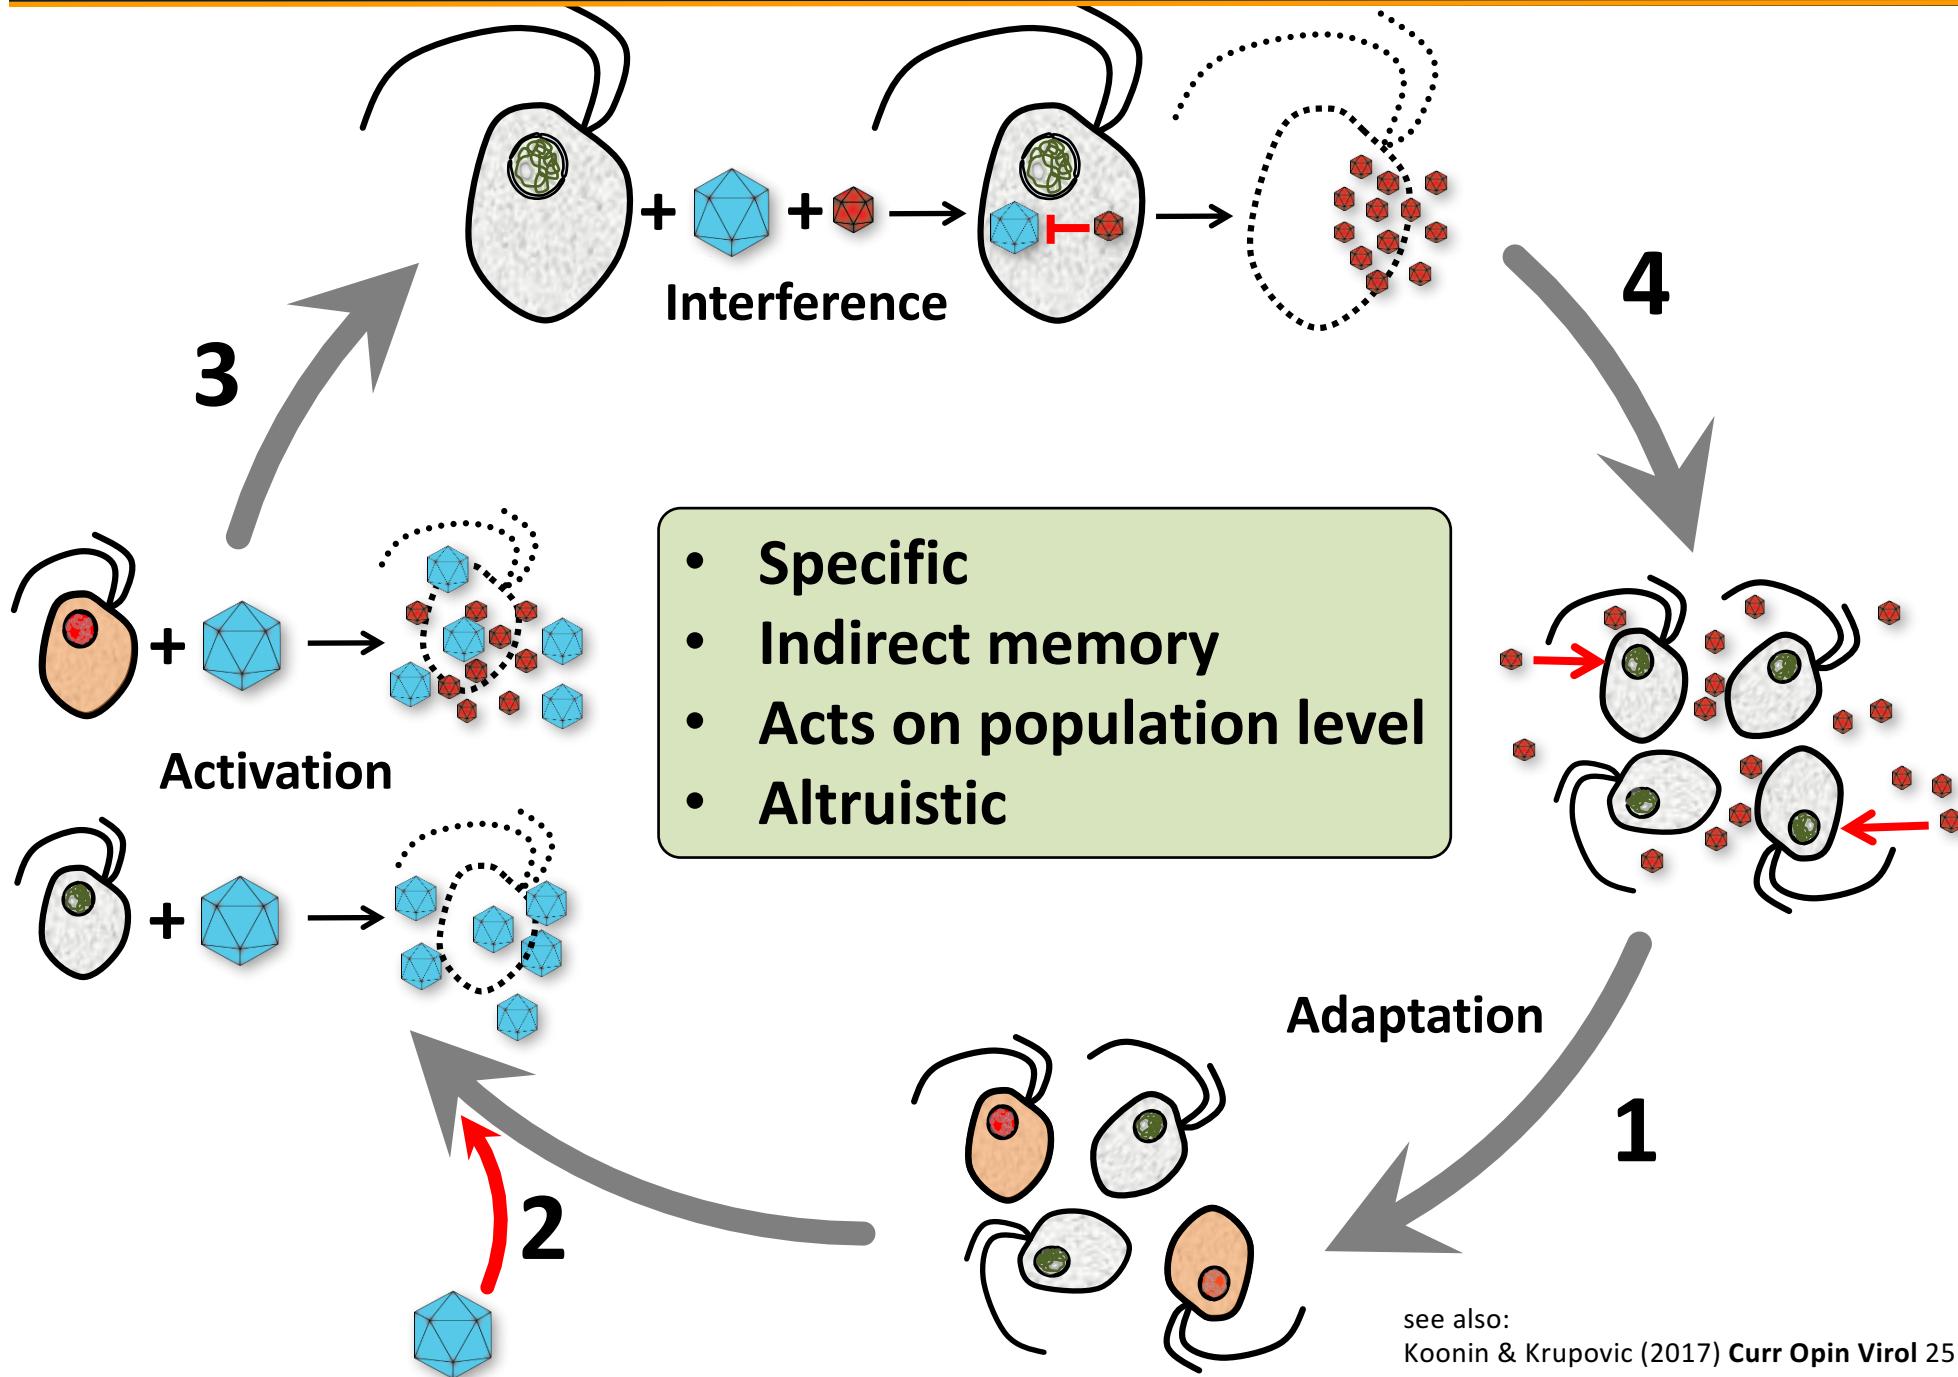

Cost imposed by endogenous virophages?

- cost of replicating an endogenous virophage genome (20 kb in 30 Mb → 0.07%)
- positional effects?
 - insertion into heterochromatin → not reactivatable
 - insertion into host genes → less fit / lethal phenotype
- multiple insertions → genomic rearrangements → instability or novelty?
- recombination with other endogenous viruses/transposons → new properties

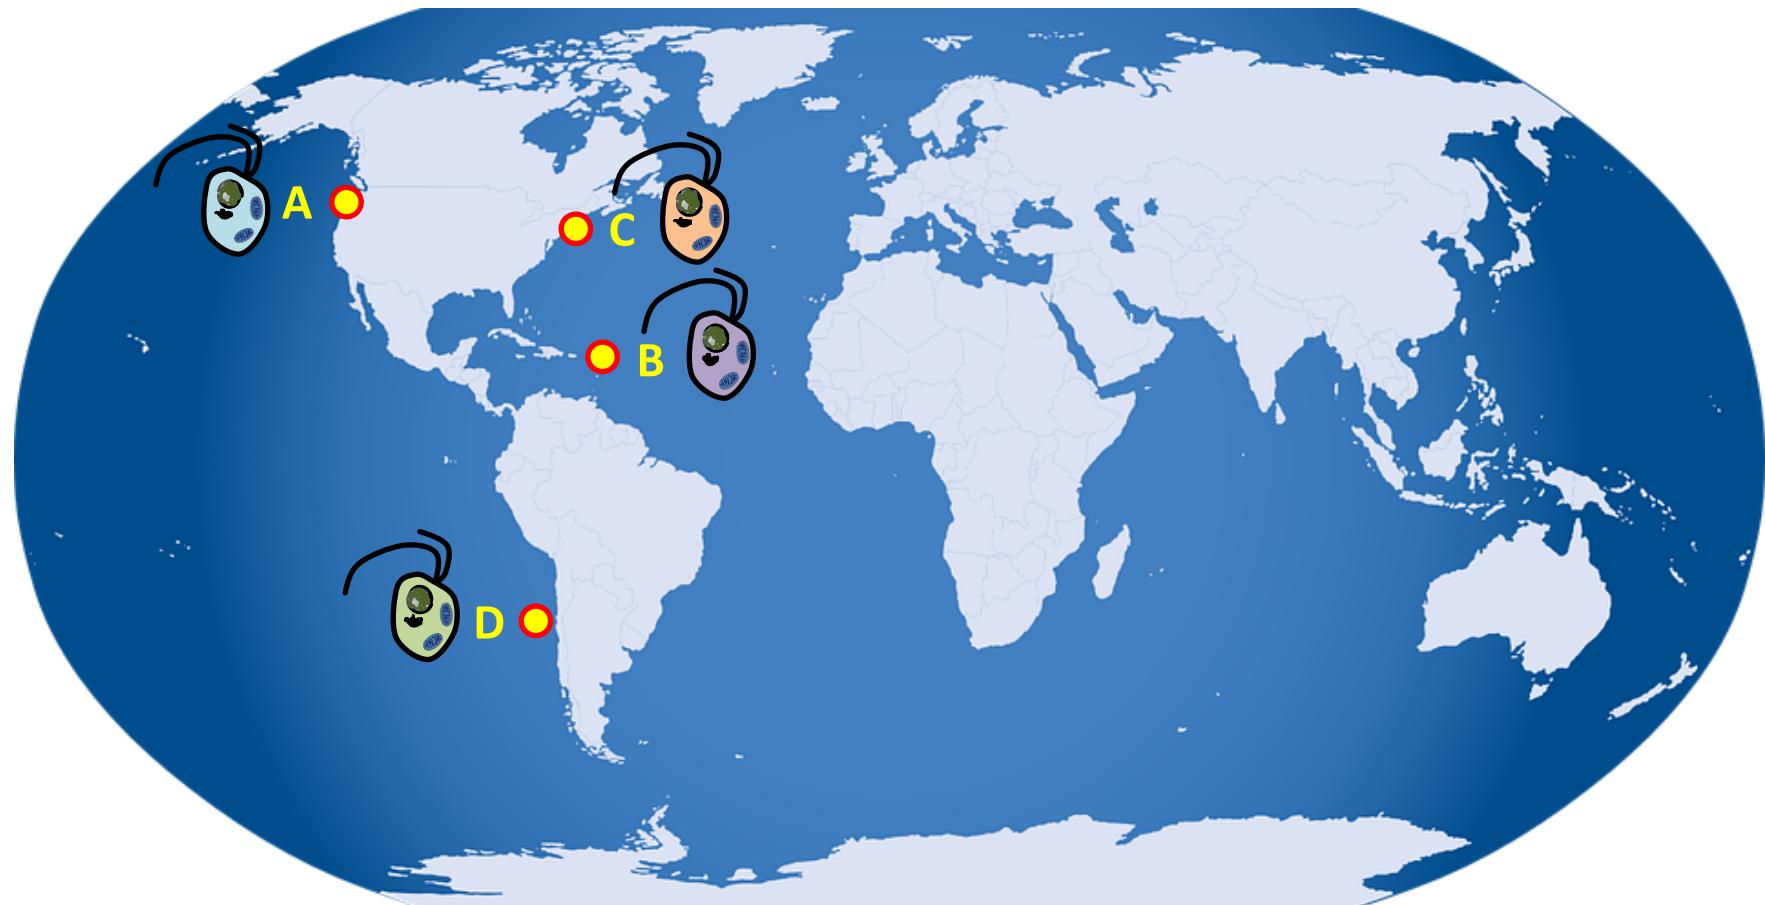

Virophages may provide adaptive population immunity

How widespread are endogenous virophages?

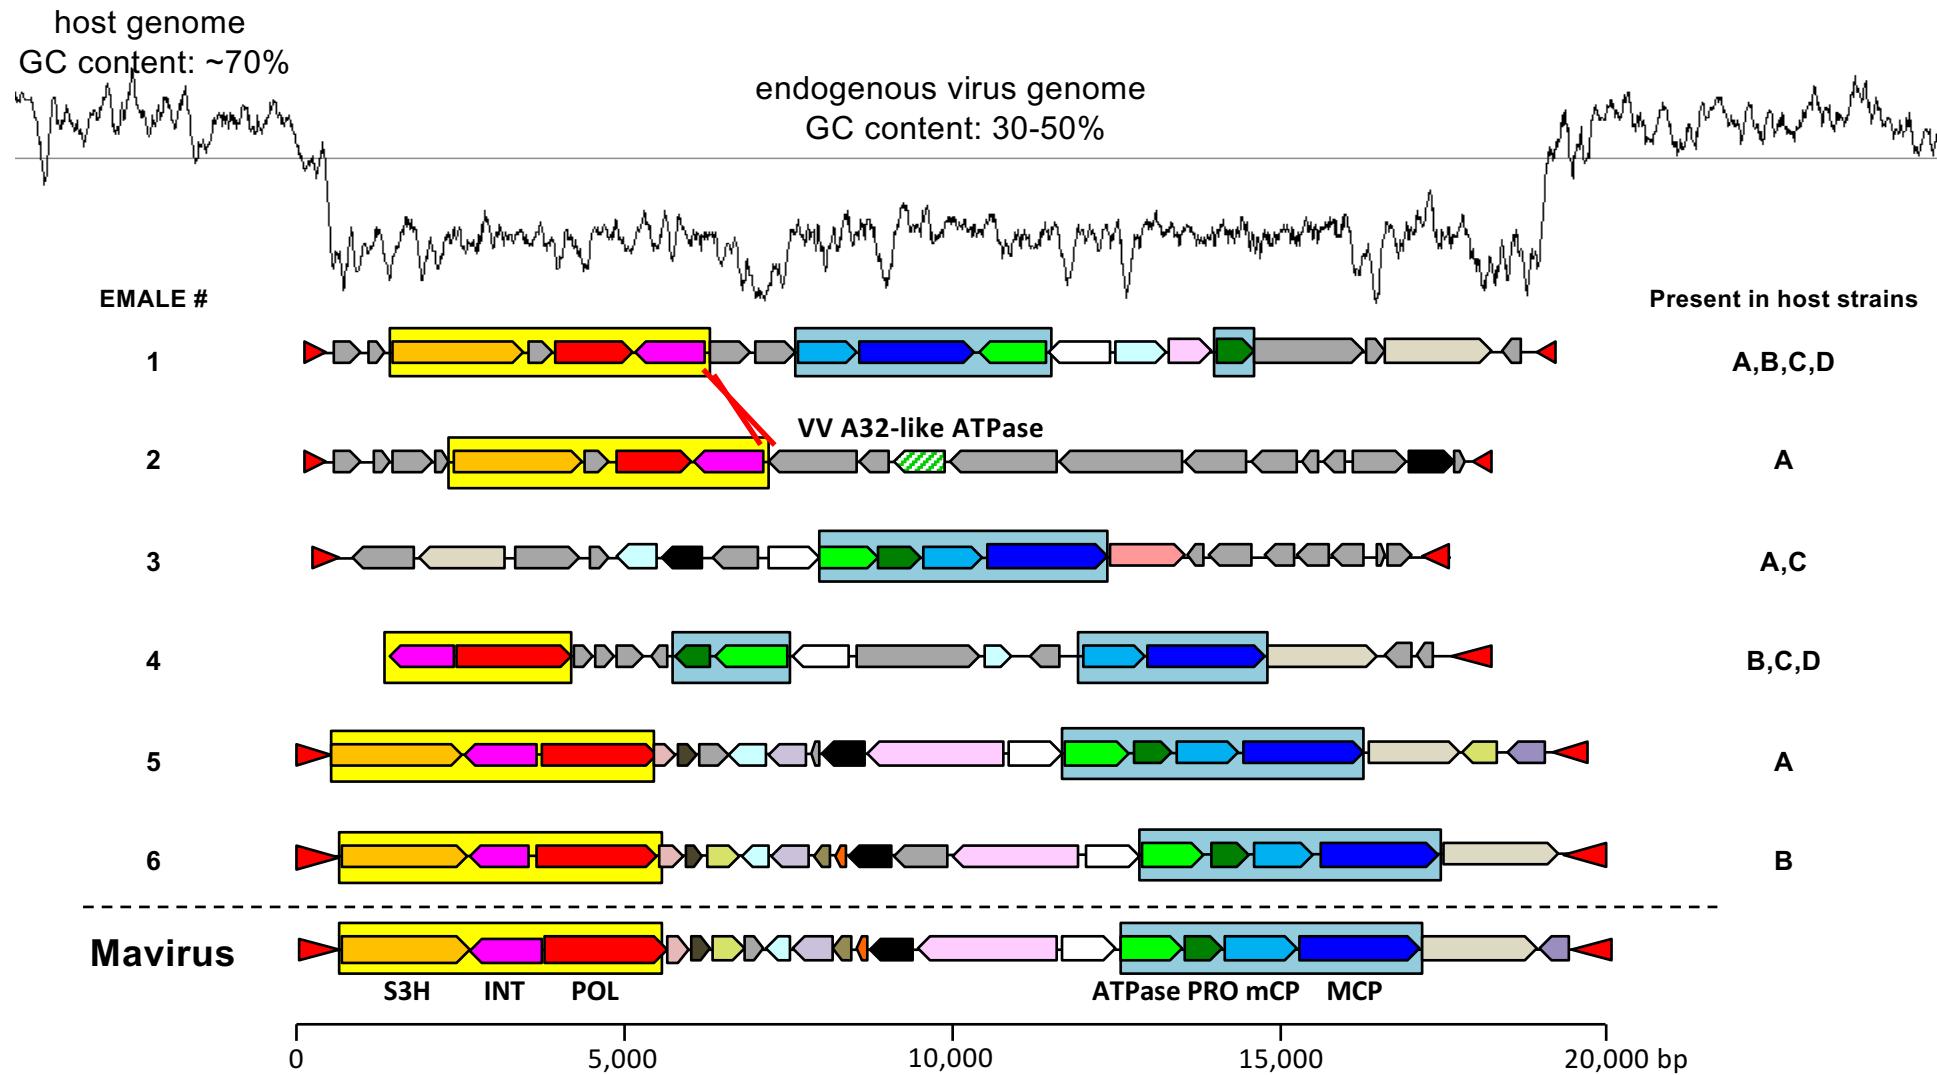

Four *Cafeteria roenbergensis* strains
Genome sequencing (MiSeq & PacBio)
Assembly (Proovread)

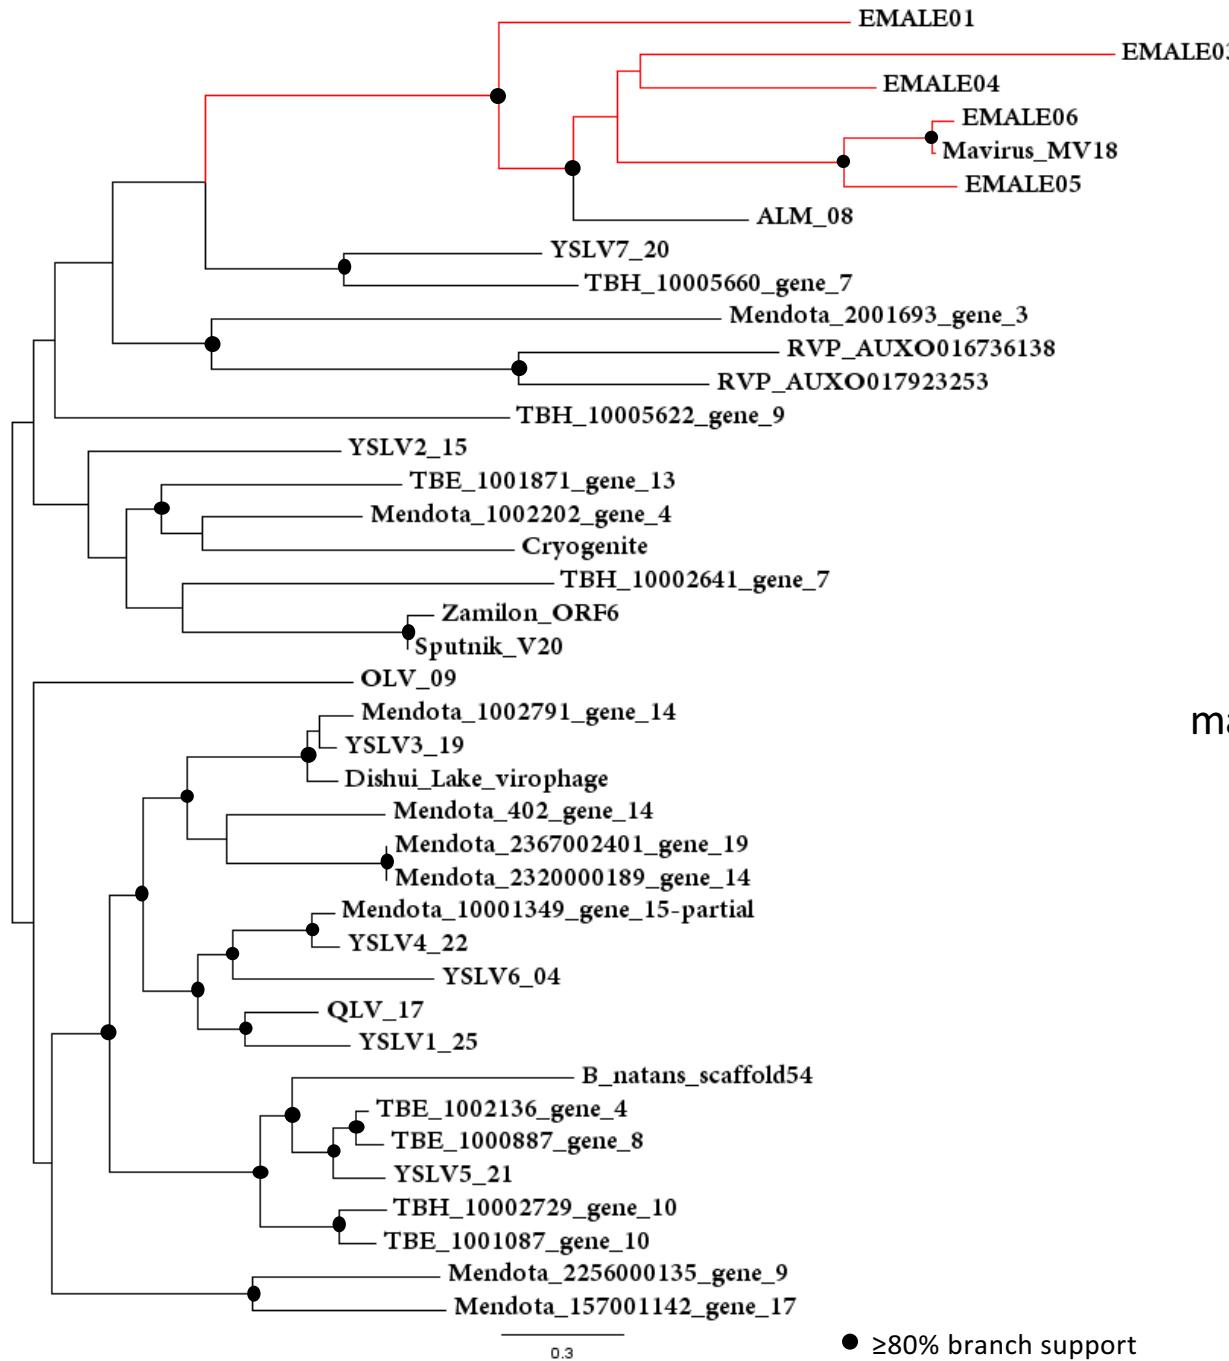

Endogenous virophages in natural *Cafeteria* strains

Six distinct versions of Endogenous Mavirus-Like Elements (EMALEs)

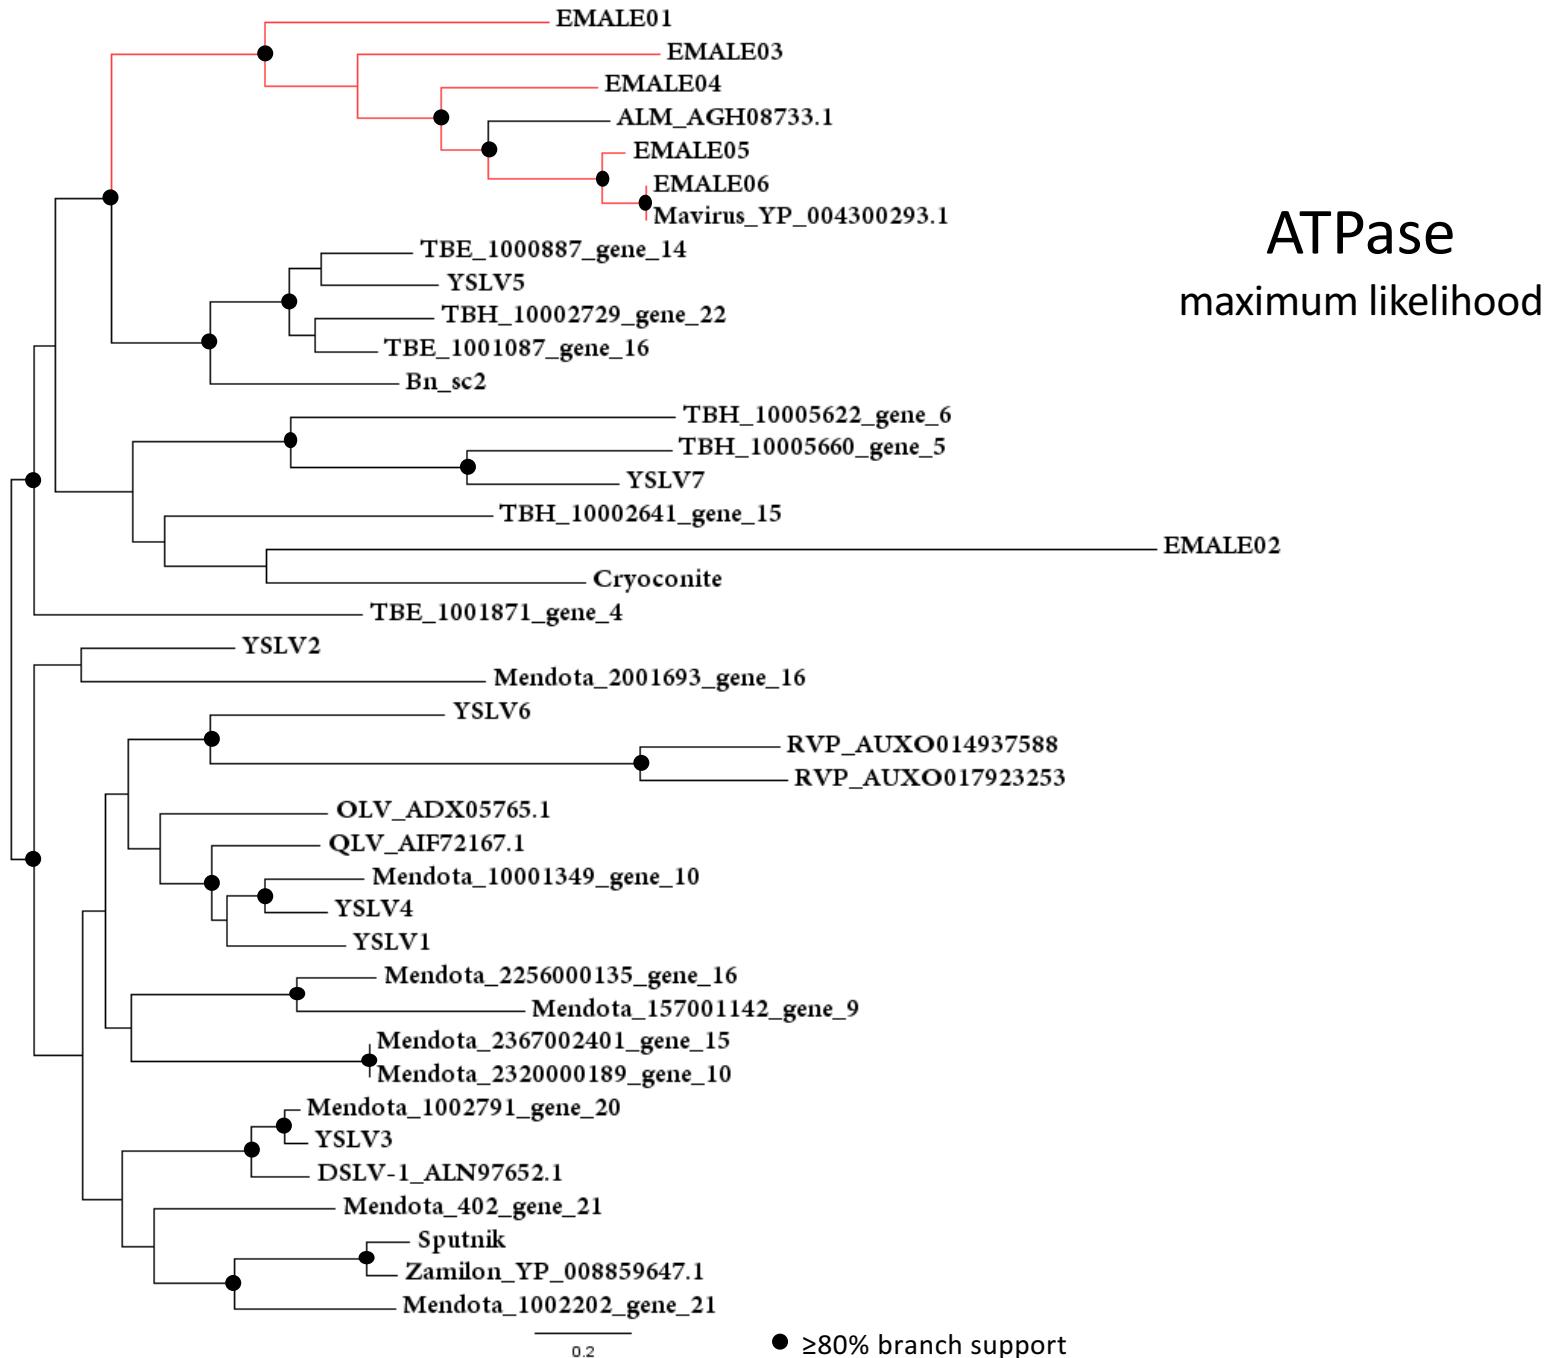

Major capsid protein phylogeny of virophages

MCP
maximum likelihood

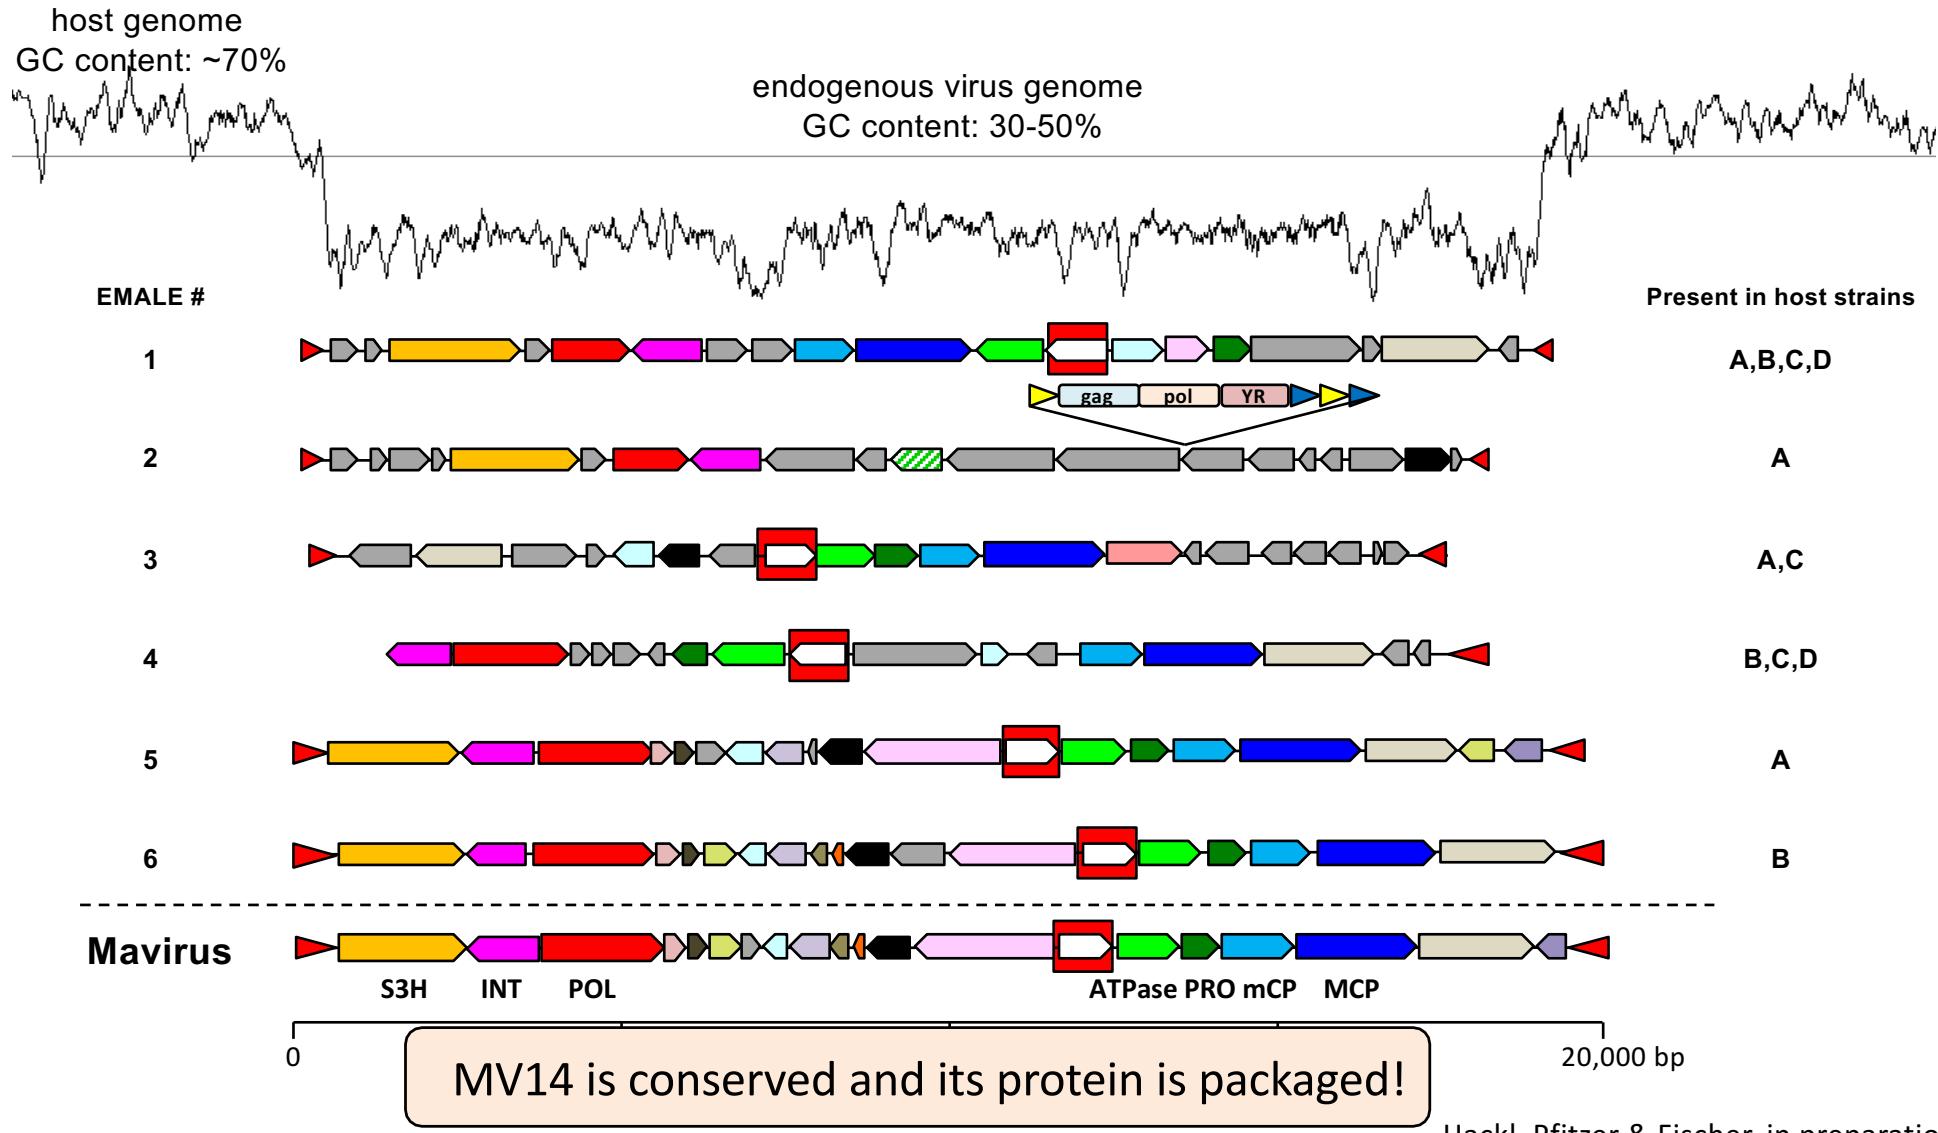

FtsK-HerA-type ATPase phylogeny of virophages

Endogenous virophages in natural *Cafeteria* strains

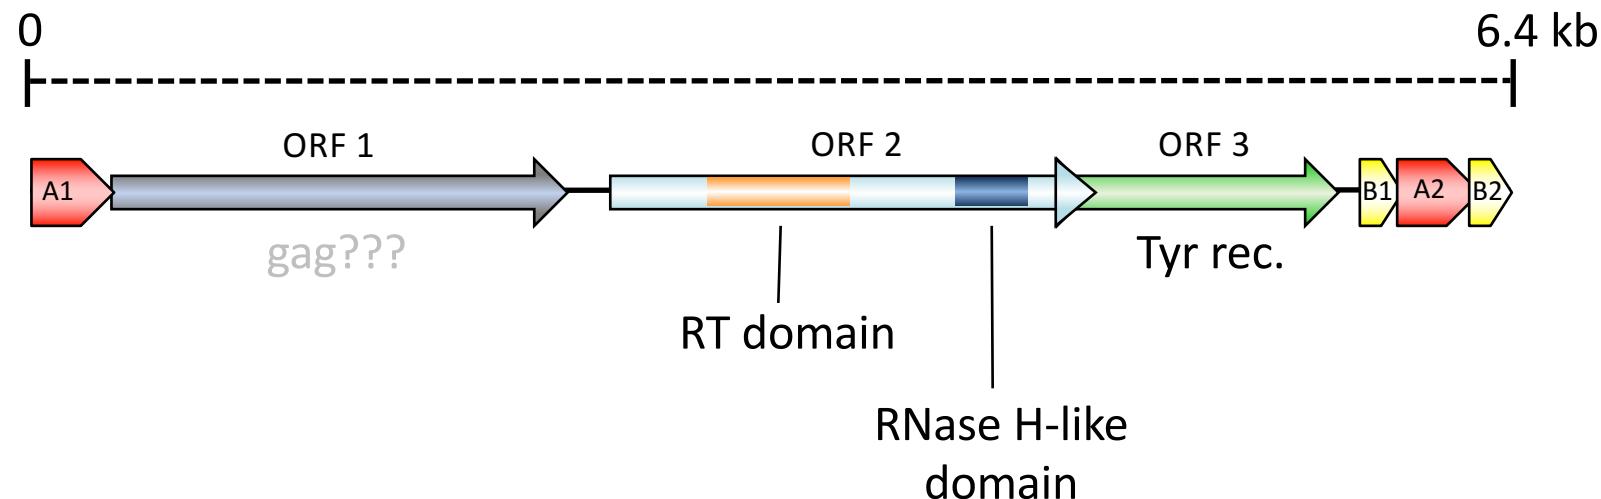

Six distinct versions of Endogenous Mavirus-Like Elements (EMALEs)

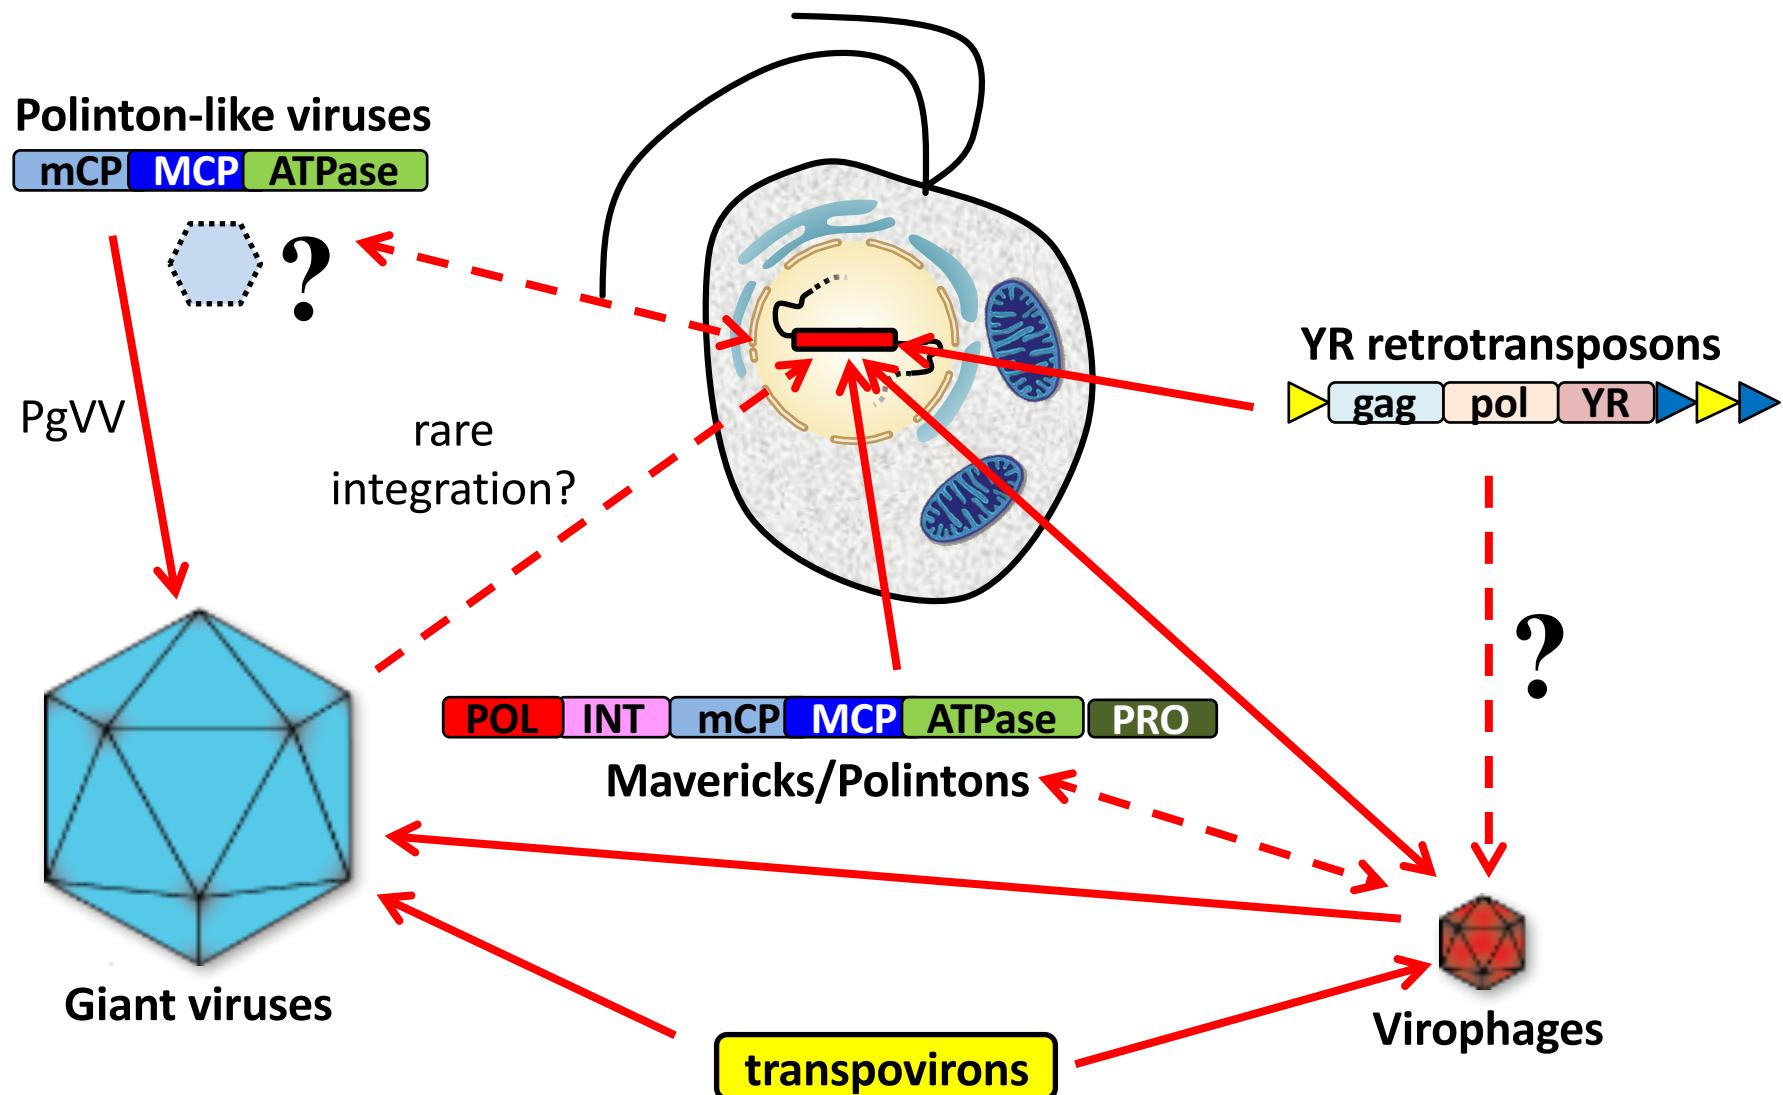

Some EMAEs carry Tyr recombinase retrotransposons

Ngaro retrotransposons (DIRS-like)
Non-LTR retrotransposons with split direct repeats

Heterotrophic protists and their mobile genetic elements

PLVs: Yutin et al (2015) **BMC Biol** 13:95

PgVV: Santini et al (2013) **PNAS** 110:10800

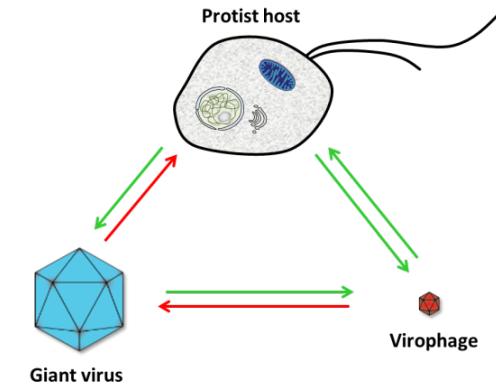

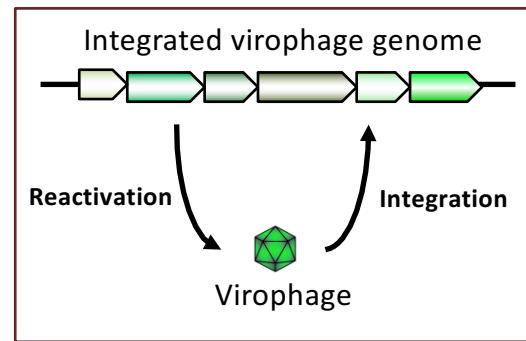

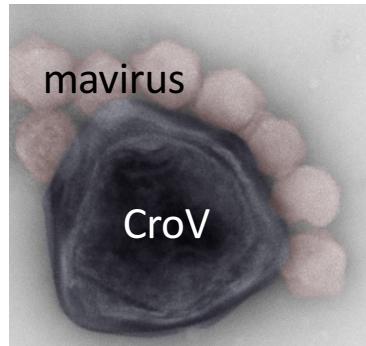

YR-RT: e.g. Piednoël et al (2011) **BMC Genom** 12:621

Transpovirons: Desnues et al (2012) **PNAS** 109:18078

Endog. giant viruses: e.g. Gallot-Lavallée et al (2017) **Viruses** 9:17

Take home points

1. Virophages are parasites of giant viruses and MGE in heterotrophic flagellates
2. Mavirus leads a dual lifestyle and displays high mobility
3. Virophages may act as an adaptive immune system in *Cafeteria*-like flagellates

Open questions:

- ecological significance?
- diversity/specifity/stability/interactions?
- virophages as HGT agents?
- ...
